All of these calculations are based on Archimedes' principle, which states that the buoyant force on the object equals the weight of the fluid displaced. This, in turn, means that the object appears to weigh less when submerged; we call this measurement the object's apparent weight.

Archimedes' principle states that the upward buoyant force that is exerted on a body immersed in a fluid, whether fully or partially submerged, is equal to the weight of the fluid that the body displaces. Archimedes' principle is a law of physics fundamental to fluid

Archimedes' principle - Wikipedia

In equation form, Archimedes' principle is $F_B = w_{fl}$, $F_B = w_{fl}$, where F_B is the buoyant force and w_{fl} is the weight of the fluid displaced by the object. This principle is named after the

Archimedes determined that an object submerged in water displaces a volume of water equal to that of the object. More importantly, he found that the buoyant force or “lifting force” on that submerged object is equal to the weight of the displaced water.

Archimedes's principle tells us that this loss of weight is equal to the weight of liquid the object displaces. If the object has a volume of V , then it displaces a volume V of the liquid when it is fully submerged.
